

ADDITIONAL FEATURES FOR THE RECENTLY DESCRIBED *PINGUICULA* (LENTIBULARIACEAE) SPECIES FROM SPAIN

AYMERIC ROCCIA • Chambéry • France • aymeric.roccia@live.fr

Keywords: *Pinguicula casperiana*, Lentibulariaceae, Serranía de Cuenca, Spain.

Abstract: Two new butterwort species, *Pinguicula casperiana* and *P. tejedensis*, from Central Spain have been recently described, and the name *P. submediterranea* has been resurrected in the same publication. My article describing “*P. conquensis*” was under review at that time and this plant is exactly the same as *P. casperiana*. As it gives additional morphological diagnostic characters, it is worth bringing it to everyone’s attention for a better understanding of this species. Additional comments are made about *P. submediterranea* and *P. tejedensis* as those populations were also studied in my article: those names are here considered later synonyms of *P. dertosensis*. *Pinguicula casperiana* raises to eleven the number of *Pinguicula* species from Spain, being the sixth endemic to the Iberian Peninsula.

Introduction

With approximately 360 species, Lentibulariaceae Rich. is the most diverse family of carnivorous plants (Fleischmann & Roccia 2018). Among these, the genus *Pinguicula* L. accounts for ca. 105 species (Juárez-Gutiérrez *et al.* 2018; Casper 2019; Zamudio & Vega 2019; Zamudio *et al.* 2019; Casper *et al.* 2020). Mexico and the Mediterranean basin represent the two main diversity centers of the genus (Fleischmann & Roccia 2018).

The last revision of the *Pinguicula* species in Spain and Portugal (Blanca *et al.* 1999) and the Flora Iberica (Blanca 2001) list nine species in the Iberian Peninsula: *P. alpina* L., *P. dertosensis* (Cañig.) Mateo & M. B. Crespo, *P. grandiflora* Lam., *P. longifolia* Ramon ex DC., *P. lusitanica* L., *P. mundi* Blanca, Jamilena, Ruíz-Rejón & Reg. Zamora, *P. nevadensis* (Lindb.) Casper, *P. vallisnerifolia* Webb, and *P. vulgaris* L. A tenth new species was added in 2018, *P. saetabensis* M. B. Crespo, Mart.-Azorín & M. A. Alonso (Crespo *et al.* 2018). Populations from central Spain have been a matter of debate: they were treated as belonging to *P. mundi* (Blanca *et al.* 1999; Blanca 2001) or to *P. dertosensis* (Roccia *et al.* 2016), or as “morphologically distinct” (Crespo *et al.* 2018).

While reviewing herbarium material, pictures from botanical fieldtrip to this region, and cultivated material, it became clear that these populations represent a new species, planned to be named “*Pinguicula conquensis*”. The article has been submitted to a peer-reviewed journal and it was only a matter of days before it should have been published. However, in the meantime, another article was realised describing two new species, *P. casperiana* and *P. tejedensis*, and resurrecting the name *P. submediterranea* (Crespo *et al.* 2020). “*Pinguicula conquensis*” and *P. casperiana* are in fact one and the same species and my article got rightly rejected for that reason. Nonetheless, it is worth adding the taxonomical features forecast in my article to the ones of Crespo *et al.* (2020) for a better understanding of this species.

Material & methods

Morphological analysis for the description of the new species is based on field observations during a fieldtrip to Spain in 2010, on examination of cultivated material, herbarium specimens held at

ALBA, BC, GADC, JACA, MA, MAF, and P (Thiers 2019) and *in situ* photographs of independent observers. The distribution map was drawn based on all those records using QGIS software in its 3.12.1 version. Conservation status is discussed following the IUCN (2012) Red List categories and criteria.

Results

Below is the description of "*Pinguicula conquensis*" as it was submitted to the peer-reviewed journal:

Diagnosis

Pinguicula casperiana is morphologically close to *P. dertosensis* and *P. mundi*. It differs from *P. dertosensis* by i) its divergent corolla lower lip lobes (vs. overlapping in *P. dertosensis*), ii) its calyx lower lip lobes fused on $\frac{1}{2}$ or more of their length (vs. free to fused on less than $\frac{1}{2}$ of their length in *P. dertosensis*), iii) the flat to slightly involute margin of its spring leaves (vs. involute margins in *P. dertosensis*), iv) its ovoid capsules with pointed tip (vs. rounded without prominent tip in *P. dertosensis*), and v) its bigger (0.65-0.8 mm long) and more rectangular seeds with micropylar appendage (vs. smaller (0.5-0.6 mm long) and subglobose to ovoid seeds without micropylar appendage in *P. dertosensis*) (Fig. 2). It differs from *P. mundi* by i) having ovoid capsules with pointed tip (vs. rounded to subglobose in *P. mundi*), ii) its shorter spur, about $\frac{1}{3}$ of the whole corolla length (vs. about $\frac{1}{2}$ in *P. mundi*), iii) its acute triangular calyx lobes (vs. rounded to subobtuse elliptic calyx lobes in *P. mundi*), iv) its shorter (up to 7(-12) cm long) summer leaves (vs. up to 18.5 cm long in *P. mundi*) and v) its smaller (0.65-0.8 mm long) seeds with micropylar appendage (vs. bigger (0.8-1.0 mm long) seeds without micropylar appendage in *P. mundi*) (Fig. 4). Additionally, the three species occur in distinct geographic areas (Fig. 3).

Etymology

Pinguicula casperiana was planned to be named "*P. conquensis*" after the Serranía de Cuenca, where it occurs. "*conquensis*" is an adjective referring to the town of Cuenca, that gives its name to the Serranía de Cuenca. "*casperiana*" is a tribute to S. Jost Casper.

Type material planned for "*Pinguicula conquensis*"

Description (Fig. 1–3)

Small perennial *herb* with slender white roots, overwintering as a hibernaculum. *Leaves* arranged in a rosette emerging from the ground; spring leaves (before anthesis) (4)-5-8 in number, yellow-greenish, sometimes tinged with red, adpressed on the ground, shortly petiolate, oblong-elliptic, abaxially glabrous, adaxially densely covered with short stipitate and sessile glands, with flat to slightly involute margins and a rounded apex, 2.5-3.6 cm long and 1.1-1.8 cm wide; summer leaves (after anthesis) different from spring leaves, (3)-4-6(-8) in number, yellow-greenish, sometimes tinged with red, semi erect, shortly petiolate, obovate, abaxially glabrous, adaxially densely covered with short stipitate and sessile glands, with revolute margins and a rounded apex, 4.5 6.9(-11.9) cm long and 1.6-2.0(-2.5) cm wide. *Flower scapes* 1-3(-4), 6.9-7.5 cm long, terete, 1-flowered, yellow-greenish and sparsely glandular at the base, red-violet and densely glandular near the flower.

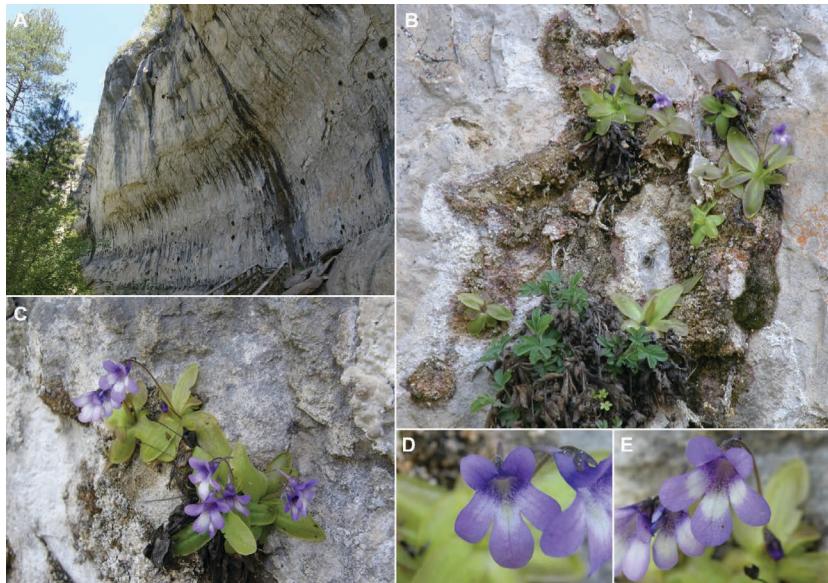

Figure 1: *Pinguicula casperiana* M.B.Crespo, Mart.-Azorín, M.Á.Alonso & L.Sáez at the Huelga de Don Juan location. A: vertical limestone cliffs, typical habitat for this species. B: plants growing in a thin layer of tufa concretion and moss, associated with *Potentilla caulescens* L. C: habit. D, E: front views of two flowers, showing variation.

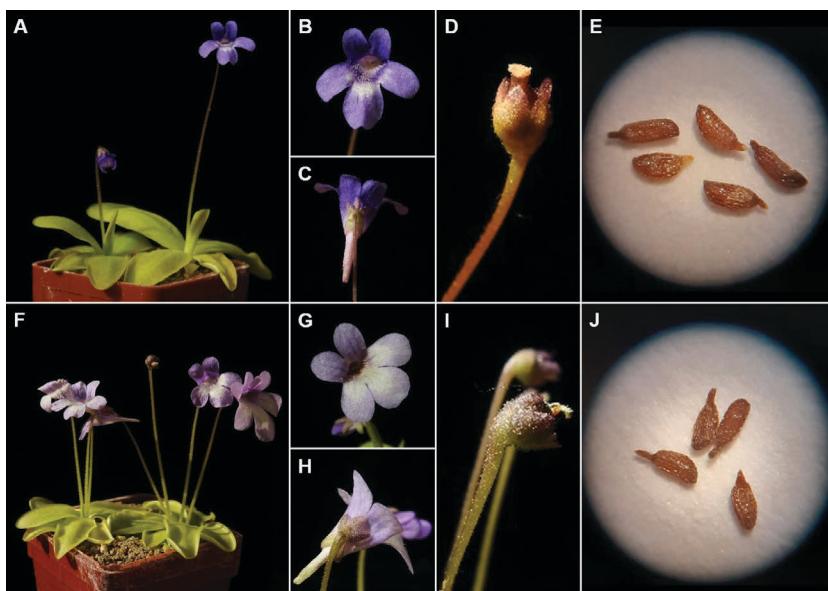

Figure 2: Comparison between *Pinguicula casperiana* M.B.Crespo, Mart.-Azorín, M.Á.Alonso & L.Sáez (A-E) and *P. dertosensis* (Cañig.) Mateo & M. B. Crespo (F-J). A, F: habit. B, G: front view of the flower. C, H: flower viewed from above. D, I: seedpod. E, J: seeds (same magnification (X20) was used for both pictures).

B. Crespo; black dot, *P. mundi* Blanca, Jamilena, Ruíz-Rejón & Reg. Zamora. Stars indicate the type locations of each species.

Figure 4: *Pinguicula mundi* Blanca, Jamilena, Ruíz-Rejón & Reg. Zamora at its type location, for comparison with *P. casperiana* M.B.Crespo, Mart.-Azorín, M.Á.Alonso & L.Sáez (Figs. 1 & 2). A: habit. B: three quarter view of the flower showing the long spur. C: seedpods. D: flowering plant showing the first elongated summer leaves. E: plant at the end of the growing season, showing the typical elongated summer leaves. C from Oliver Gluch, all others from the author.

Calyx bilabiate, 5-lobed, violet, densely covered with stipitate glands, persistent during fructification; 3 upper lip lobes triangular-ovate, with an acute to subacute apex, 3.0-4.0 mm long, 1.0-1.5 (-2.0) mm wide, divided to near the base; 2 lower lip lobes ovate, with an acute to subacute apex, 3.0-4.5 mm long, (1.0-)1.5-2.0 mm wide, united from the base on c. $\frac{1}{2}$ of their length, subparallel to slightly divergent. *Corolla* bilabiate, 5-lobed, 20-30 mm long (spur included), blue-violet in its overall, with a 90-110° opening angle; 2 upper lip lobes blue-violet, sometimes marked with a dark blue-violet vein at the base, oblong, with a rounded apex, 4.0-5.5(-7.5) mm long, 3.0-4.5(-7.0) mm wide; 3 lower lip lobes blue-violet on the distal part, white on the proximal part (sometimes the lateral lobes completely blue-violet) and sometimes marked with dark blue-violet veins near the throat, bearing c. 0.75 mm long white clavate hairs on the proximal part, the lateral ones oblong-obovate with a rounded apex, longer than wide, 5.0-8.0(-10.0) mm long, 4.0-7.5 mm wide, the middle one larger than the lateral ones, obovate with a rounded apex, sometimes with a yellow spot at the very base, 7.5-11.0 mm long, 6.0-9.0(-11.0) mm wide, divergent, not overlapping, with non-waving margins. *Throat* totally dark violet, except a thin whitish band on top of the middle lobe of the lower corolla lip, bearing c. 0.75 mm long white clavate hairs. *Tube* medium-sized, 5.5-8.5(-11.5) mm long, (4.0-)6.0-8.5(-10.5) mm wide, broadly funnel-shaped, blue-violet near the corolla lobes, violet tinged with red near the spur and whitish with dark violet veins on the lower side, sparsely covered by stipitate glands on the outer side. *Spur* blue-violet to red-violet, medium-sized, 5.5-7.0(-9.5) mm long, subulate, straight to slightly curved downwards, with an acute and sometimes slightly bifid apex, sparsely covered by stipitate glands on the outer side. *Stamens* 2, c. 2 mm long; filaments c. 1.5 mm long, white, curved, surrounding the ovary; anthers c. 0.5 mm long, light yellow, +/- confluent, roofed by the stigma lower lip lobe. *Pollen* light yellow, aperture not studied. *Ovary* pale green, subglobose, sessile, covered by short stipitate glands, c. 1.5 mm in diameter, 2-carpellate, 1-loculate, ending in a short style; central placentation free, with numerous free sessile ovules. *Stigma* white tinged with violet, short, 2-lobed, with crested upper surfaces, persistent on the fruit; the lower lobe ovale, c. 2 mm wide, fringed; the upper lobe much smaller, narrowly triangular, c. 0.75 mm long, not fringed. *Capsule* yellow-greenish at the base, usually tinged with red mostly near the tip, ovoid with acute tip, 3.0-4.5 mm long and 2.0-2.6 mm large, sparsely covered by short stipitate glands; maroon when mature and then dehiscent. *Seeds* brown, elliptic to oblong, 650-800 μm long, 230-300 μm thick, stipitate with a 110-135 μm long funicle, outer coat reticulate with subrounded to ovale interspaces, with a single very short micropylar appendage (10-30 μm long). *Chromosome number* $2n = 64$ (Casper & Stimper 2009).

Phenology

Pinguicula casperiana starts flowering in April and can flower up to June.

Habitat and ecology

Pinguicula casperiana is typically found on vertical limestone cliffs, in deep humid gorges, at an altitude of 860-1220 m a.s.l. Plants are growing in a thin layer of tufa concretion and moss, accumulating in rock crevasses where water seeps from the cliff. It is usually growing alone but can share such habitat mainly with *Potentilla caulescens* L., and sometimes with *Adiantum capillus-veneris* L. (Fig. 1).

Distribution

Pinguicula casperiana is endemic to the Serranía de Cuenca, in central Spain. Most populations occur in the Cuenca province, and a few locations are also known in the Guadalajara province

(Fig. 3). Up to now, no reference to its presence in the nearby Teruel province have been found, but it has to be searched in the east of this province.

It has been observed a morphological gradient for *Pinguicula casperiana* leaf along its distribution range: to the north, summer leaves are different from spring leaves (anisophyllous), being longer and with revolute margins, while towards south, they tend to be rather identical to spring leaves (heterophyllous), being shorter and with involute margins.

Conservation status

It was not possible to investigate the number of plants in each known location in the timeframe of this study, so that *Pinguicula casperiana* should be classified at DD (data deficient) (IUCN 2012). However, comparing photographs of the same sites (Huelga de Don Juan and Hoz de Priego) taken several years apart, it is obvious that the number of plants decreases as the cliffs are becoming drier. The vulnerability of *Pinguicula casperiana* has thus to be further investigated.

Additional specimens examined

Discussion

Pinguicula casperiana has been treated diversely in the past. In Blanca *et al.* (1999) and the subsequent chapter of Flora Iberica (Blanca 2001), it was considered as northern populations of *P. mundi*. However, as stated above in the diagnosis, it can be morphologically distinguished by leaf, flower, fruit and seed characters (Figs. 2 & 4). Later, Roccia *et al.* (2016) treated these populations as *P. dertosensis*, but *P. casperiana* also differs from this last one by a number of vegetative, floral and reproductive diagnostic characters described in the diagnosis (Fig. 2). Thus *P. casperiana* truly represents a morphologically distinct species in the Iberian Peninsula, further supported by its geographically distinct distribution range (Fig. 3).

Pinguicula casperiana chromosome number was first studied by Casper & Stimper (2009), based on material from the Hoz de Beteta (quoted as *P. cf. vulgaris* "Hoz de Beteta"). With $2n = 64$, it is an octoploid species and cannot be caryologically discriminated from *Pinguicula dertosensis* and *Pinguicula mundi*. Those two were first reported as hexaploid species (Zamora *et al.* 1996), but Casper & Stimper (2009) have not been able to confirm these results. It was then hypothesized that they all three belong to a "*P. vulgaris*-like" group of species from central Spain (Casper & Stimper 2009). However, a recent ITS-based molecular phylogeny study showed that *P. dertosensis* and *P. mundi* are well separated within the phylogenetic tree of European species, belonging to E1a and E3a subclades, respectively (De Castro *et al.* 2016). The recently described *P. saetabensis*, another species from Central Spain, is phylogenetically related to *P. mundi* (Crespo *et al.* 2018). Unfortunately, *P. casperiana* samples were not included in those two studies. Studying DNA material of *P. casperiana* would show if it is more related to *P. dertosensis* or to *P. mundi*.

The exact expansion to the east of *Pinguicula casperiana* has still to be explored. As said before, no population in the Teruel part of the Serranía de Cuenca has been found during fieldtrips, in the herbaria or in the literature. However, some locations exist between the Serranía de Cuenca and the Massís dels Ports and have to be investigated to decipher if they belong either to *P. casperiana*, *P. dertosensis* or another species. For example, the population in Iglesuela del Cid (Teruel province) has been a matter of debate. It was long thought to be *P. dertosensis*, but a recent report discards this possibility and rather assigns it to *P. vulgaris* (López Udiás *et al.* 2016). However, such populations have not been visited by the author for the present study. Photographs sent by López Udiás (pers. comm., 2020) depict a phenotype closer to *P. vulgaris* than to *P. casperiana* or *P. dertosensis*, but somehow peculiar compared to "typical" *P. vulgaris*. Such populations have to be investigated in a geographically wider study, especially comparing it to *P. vulgaris* L. var. *alpicola* Rchb., *sensu* Legendre *et al.* (2014).

A similar matter appears when it comes to the swampy populations of *Pinguicula*, in the Montes Universales, around the triple point Cuenca/Guadalajara/Teruel. The voucher MA-01-00589325 was identified as belonging to *P. mundi* in Blanca *et al.* (1999). This voucher was made from a fruiting specimen. However, the seedpod does not correspond neither to *P. casperiana* nor to *P. mundi*, but could match to the one of *P. dertosensis*. One population, at the Rio Júcar source, has been

investigated for the present study. Flowers in fact look intermediate between *P. casperiana* and *P. vulgaris*. It can be hypothesized that *P. casperiana* actually represents the saxicolous populations of the Serranía de Cuenca, while another possible new taxon occupies the swampy areas of the Montes Universales, but this point still has to be more closely investigated. In this respect, additional populations assigned to *P. vulgaris* in literature and herbarium vouchers, growing in the surroundings, would need to be investigated too.

Additional comments and discussion

As can be seen in this extract, this article was in full agreement with Crespo *et al.*'s (2020) opinion that *Pinguicula casperiana* is a distinct species from *P. dertensis* and *P. mundii* and it gave additional diagnostic characters to discriminate them. Of course, although not explicated, "*P. conquensis*" was also considered to be different from the superficially similar *P. vallisneriifolia* and *P. saetabensis*. However, I do not consider *P. submediterranea* and *P. tejedensis* as distinct entities from *P. dertensis*. Although it was one point I also thought to address in my article, I was not able to find any significant diagnostic character after reviewing many vouchers and pictures. The main morphological difference of *P. submediterranea* claimed by Crespo *et al.* (2020) is the smaller size of the plants in all aspects. In table 1, *Pinguicula tejedensis* and *P. submediterranea* seedpods are claimed to be oblong-ovoid, the which I cannot confirm from voucher and picture examination and from their figure 1 (see also Figure 2 in this article for comparison with *P. dertensis*). The difference in seed shape is also not obvious (compare their figure 4 with Figure 2 in this article for comparison with *P. dertensis*). Thus, *P. submediterranea* and *P. tejedensis* can be regarded as later synonyms of *P. dertensis*.

The main focus of Crespo *et al.*'s study (2020) is on molecular phylogeny. *Pinguicula casperiana* is genetically closely related to *P. dertensis*, but, as seen above, it is morphologically distinct. *Pinguicula submediterranea* and *P. tejedensis* appear genetically distant from *P. dertensis*, although they are morphologically identical. A similar matter already occurred when describing *P. lattanziae* (De Castro *et al.* 2016). Unfortunately, Crespo *et al.* (2020) did not describe their protocol in the material and methods, but seemingly used the same as they did in Crespo *et al.* (2018), which is based on De Castro *et al.*'s (2016) material and methods. Sanger sequencing is problematic when analyzing nuclear markers of polyploid organisms. The obtained sequence is a mix of several (up to eight in the case of this group of octoploid butterwort species) sequences and thus the final result greatly depends on the interpretation of the person who analyzes the raw data. This experimenter bias will therefore also affect the subsequent molecular phylogeny analysis. Although nuclear markers will probably prove to be very useful, recent results have shown the limits of the currently applied method that is only able to discriminate groups of species, but has to be considered very cautiously at the species level. As it is, such analyses may be used to support morphological differences, but should not be the base for describing new species. A different experimental method should lead to more significant results. I designed such a protocol (unpubl.) but I hadn't yet the opportunity to apply it to butterworts. However, independent similar experiments gave interesting results on ferns (Rothfels *et al.* 2017), moonworts (Dauphin *et al.* 2018) and quillworts (Grigoryan *et al.* 2020), for example.

Acknowledgements: Eric Partrat and Laurent Legendre are thanked for useful fieldtrip pictures and accession to cultivated material. Eric Partrat is also thanked for useful discussions about *P. casperiana*. Iwein Coppens was part of the 2010 fieldtrip is thanked for driving long way down to Spain. Oliver Gluch is thanked for providing one picture to complete Fig. 4. ALBA, BC, GADC, JACA, MA and MAF curators are thanks for their kind assistance in examine their vouchers.
